Criterion A: Planning

1. Defining the problem

My client, Ryan Zhang, an LOHS TV gameday commentator, wants an easy way to record the stats for every player on the Lillian Osborne basketball team. Problems include inaccurate stat tracking and limited stat recording. I held an interview with Ryan for him to understand the program that is being made and how the program will be used.

A solution that I proposed is to make a database to store data while displaying the stats in a nice table. The program will be user friendly and easy to input information.

I will hold a second interview with Ryan to better understand how he wants to use the program and give him an idea on how the finished product will look.

2. Rationale for proposed product

The idea of the program is to store and display information, as well as calculate averages. The program will be a user-friendly way for Ryan to view stats of players.

I believe that SQL and Python is a simple way to achieve this. I will be using the “sqlite 3” library in Python, as well as “tabulate” for displaying tables, and “numpy” for calculations.

SQL is a language that I am familiar with and have little problem managing a database with SQL.

3. Success criteria

- Program will display a menu
- Program will display data in a nice table
- Program will ask for the name of the player to be added
- Program will ask for a value to be inputted for a stat
- Program will be able to display the names of every team member
- Program will be able to calculate averages
- Program will restart without the user having to restart it manually
